

Migration Guides

Migrate Windows computers from source Active Directory to target Active Directory - no App reconfiguration

Valid for version 3.3x

Introduction

This Migration Guides is an aide memoir, and the intended audience is experienced migration Engineers. It does not capture all use cases and scenarios. You may need to tailor your Runbooks and Batch configurations for your particular project and requirements

This use case is typically used after Microsoft 365 workloads have already been migrated and cloud identity is already aligned in the target tenant.

Below are the high-level steps that you should review and complete at a minimum to migrate a Windows 10 or 11 computer, where Microsoft 365 Apps have already been reconfigured on a workstation, but the device has remained in its home / source Active Directory and now needs to be migrated to the final end-state Active Directory, but the apps do not need reconfiguring.

USE CASE:

Migrate workstations AD to AD with no App reconfiguration following a tenant-to-tenant migration

You might be migrating computers from:

SOURCE	TARGET
Active Directory Domain joined	Active Directory Domain joined (With or without Hybrid Entra join).

PowerSyncPro cannot force Hybrid join or Intune Enrol. This still requires your own target environment configured correctly. Workstations cannot successfully Hybrid Join until they contact a target Domain Controller.

These instructions should be read in conjunction with the latest Configuration Guide <https://downloads.powersyncpro.com/current/PSPMA-ConfigurationGuide.pdf>

STEPS

Create and Configure Directories

Create your source and target directories that you will be working with. You will need to have created an Entra App Registration in advance for any Microsoft Entra ID Directories. You will need:

- Source AD
- Target Entra ID

You must ensure that you have scoped the Import Object Types to a minimum of Users, Groups and computers.

Create a Sync Profile for Migrating Users

You must have at least a “Match Only” sync profile with correctly scoped Users and Groups that are your target for Windows workstation Migrations that have an active Windows profile that will require repermissioning. For repermissioning to happen there must be a User Translation Table, and that is built via the Sync Profiles.

It is typical in AD-to-AD migrations that you would have fully fledged DirSync profiles running as “Create & Update” that are also suitable for generating a Translation Table.

Enable the DirSync Schedule

Configure and enable the sync schedule to ensure that Users and computers will be imported into the PowerSyncPro Database for you to work with.

Obtain and apply a licence

You will not be able to migrate any workstations without a valid licence. You must be accurate with your domain FQDN and / or Microsoft 365 Tenant information when procuring your licence. Apply the licence at Global Settings\Licences option.

Run an end-to-end DirSync

Be sure that an end-to-end sync cycle has run including Import, Sync and Export

Message Logs

Check the Message Logs for **Warning and Errors**. Confirm or remediate any unmatched users

What If

Confirm the **What If** report has been checked and accepted so that DirSync will run in steady state on the schedule.

Check the Translation Table

Go to the **Translation Table** view (Migration Agent\Reports\Translation Table) and spot check any users that you know are in scope for migration. If your migrating users do NOT appear in the translation table, then **do not migrate their device**. It will **NOT** be re-permissioned.

Single Object Report

Use the single object report to spot check and search for a user or computer you are migrating.

Migration Agent Configuration

Create a pre shared key

The pre-shared key is mandatory requirement for the installation of the Migration Agent on the computer. This sets-up the initial secure channel communication.

Create a Certificate

The private certificate is mandatory requirement for the installation of the Migration Agent on the computer. This ensures that all communication between the workstation and the PowerSyncPro server is secure and encrypted.

Create Runbooks

A Runbook contains all the instructions for the Migration Agent to execute on the computer including the device join state, Intune enrolment, Windows profile repermissioning, application reconfiguration and any pre and post migration scripts.

We advocate only having one primary runbook and one prerequisite Runbook unless you explicitly need to achieve different outcomes for different batches of users and computers. Use your single Runbook and any prerequisite Runbook in any Batches you have, even if they are Early Adopters, Pilot and Main migration waves and events.

Main Runbook

- **Name:** Choose any meaningful label you like. This will be seen in reports, dashboards and logs.
- **Source Directories:** This should be your source Active Directory
- **Target Directories:** This should be your target Active Directory
- **Startup:**
 - **User Interaction** should be set to "Show Progress" and
 - **Do Not Run Startup** should NOT be selected.
 - **Be sure to configure:** An Admin fallback account, any custom pre-migration scripts, Legal Notice, Prevent Login and a Lock Screen image. PowerSyncPro can provides a default image if you prefer.
- **User Experience:** You should choose your own wording here for what your end users will see and if you need to create additional languages (Culture). You can accept the defaults. If you will use Offline Domain Join with Cache Credentials you should customize this option. If you use Cache Credentials you should configure this is a prerequisite runbook. See the Offline Domain Join migration guide.
- **Device State:** When migrating from Active Directory to another Active Directory you should ensure that on the device State tab you will need:
 - **Remove From: Active Directory**

- Only choose All Directories here if you will be also changing the Entra join state. If you have already configured the computer to Hybrid join to target you do not need to remove it from Entra again
- **Domain join: Active Directory**
- **Permission Updates:** You must ensure that **add and remove permissions** is selected
- **App Reconfiguration:** Apps do not need to be reconfigured for this scenario. Users are already connected to the target tenant to consume their workloads.
- **Completion:** Any post migration scripts

Create a Batch

Batches contain the list of computers in scope, the Runbooks to execute and the start time and date.

- **Name:** Choose any meaningful label you like. This will be seen in reports, dashboards and logs.
- **Source Directory** is your Source AD
- **Target Directory** should be your Target AD
- **Available From Time** When selected, the workstation agent shows a dialog notifying the user their migration is ready to run from this date/time onward. The user can start the migration or click Snooze to defer (Snooze is the only way to dismiss the dialog).
- **Enforced After Time** The mandatory run time. If the machine is on, no user is logged in, and the PowerSyncPro server is reachable, the migration starts within 15 minutes of this date/time.

For testing and early adopters: You can create your batches with an **Enforced After** date far in advance if necessary but then have the **Available from** closer to your present time to facilitate self-service migrations and testing. For Production migrations you should settle on the actual date you will use.

Batches can have multiple Runbooks

Do not have computers in multiple Batches.

Adding a computer to Batch less than 24 hours before migration is unlikely to be successful unless you restart the PowerSyncPro on the Computer. Always ensure that you have a valid and populated

Confirm a working migration endpoint URL

If you are using IIS with a reverse proxy your endpoint will be https (TCP port 443) using your friendly DNS name and a valid SSL certificate binding. E.g. <https://powersyncpro.contoso.com/Agent>

To test: From an in-scope computer open the browser and connect to the URL this should resolve successfully to a landing page

If you are using the *default installation*, then your endpoint will be the PowerSyncPro server FQDN with TCP port 5000. Typically, this would be only used for your initial end-to-end testing. E.g. <http://pspsserver.contoso.local:5000/Agent>

The PowerSyncPro server endpoint URL must be available at the start of the migration to confirm the latest runbooks and scheduling information, and critically to get SID translation data from the server during the migration. Once the computer migration has started, reporting information such as migration status and logging will be written back to the server.

Agent Installation

The .NET 8.x Desktop Runtime prerequisites must be installed. These can be installed separately in advance or bundled with the complete PSP Migration Agent Installer. It is more common to use the bundled version.

Agent Registration

Confirm that Agents are successfully registering on the PowerSyncPro server by reviewing the Agents view and Failed Communications report.

Checklist

TASK	COMPLETE
Create and configure Directories	
Create and configure Sync Profile for Users and Groups	
Enable the schedule	
Obtain and apply a software licence	
Run an end-to-end Import/Sync/Export	
Check Message Logs for Warnings and Errors	
Confirm the What If report	
Spot check the Translation Table	
Spot check the Single Object Report	

Agent Preparation	COMPLETE
Create a pre shared key and Certificate	
Create Runbooks and Batches – including prerequisite Runbooks	
Confirm a working PowerSyncPro server endpoint URL	
Confirm Microsoft 365 tenant Entra join and Intune Enrol settings	
Confirm Agent Installation with prerequisites	
Confirm Agent Registration and profile harvests	
Test with non-production users and computers	

Documentation

We take a lot of pride on the documentation. If you follow the guides, we believe that you should be able to get yourself up and running. <https://powersyncpro.com/documentation>

Knowledge Base

We are regularly adding and updating articles in the Knowledge Base, so also try here as a good resource. <https://kb.powersyncpro.com/>

Support

Support is available from: <https://tickets.powersyncpro.com/>

If you are logging a ticket, be prepared to send the Migration Event Logs plus Windows Application Event logs from the affected computer and the Server / Agent version.
